**Estrogen** or **oestrogen** ([see spelling differences](#)) is a category of [sex hormone](#) responsible for the development and regulation of the female [reproductive system](#) and [secondary sex characteristics](#).<sup>[1][2]</sup> There are three major [endogenous](#) estrogens that have estrogenic hormonal activity: [estrone](#) (E1), [estradiol](#) (E2), and [estriol](#) (E3).<sup>[1][3]</sup> Estradiol, an [estrane](#), is the most potent and prevalent.<sup>[1]</sup> Another estrogen called [estetrol](#) (E4) is produced only during pregnancy.

Estrogens are synthesized in all vertebrates<sup>[4]</sup> and some insects.<sup>[5]</sup> Their presence in both vertebrates and insects suggests that estrogenic sex hormones have an ancient evolutionary history. Quantitatively, estrogens circulate at lower levels than [androgens](#) in both men and women.<sup>[6]</sup> While estrogen levels are significantly lower in males than in females, estrogens nevertheless have important physiological roles in males.<sup>[7]</sup>

Like all [steroid hormones](#), estrogens readily [diffuse](#) across the [cell membrane](#). Once inside the cell, they bind to and activate [estrogen receptors](#) (ERs) which in turn [modulate](#) the [expression](#) of many [genes](#).<sup>[8]</sup> Additionally, estrogens bind to and activate rapid-signaling [membrane estrogen receptors](#) (mERs),<sup>[9][10]</sup> such as [GPER](#) (GPR30).<sup>[11]</sup>

In addition to their role as natural hormones, estrogens are used as [medications](#), for instance in [menopausal hormone therapy](#), [hormonal birth control](#) and [feminizing hormone therapy](#) for [transgender women](#) and [nonbinary people](#).

Synthetic and natural estrogens have been found in the environment and are referred to as [xenoestrogens](#). Estrogens are among the wide range of endocrine-disrupting compounds (EDCs) and can cause health issues and reproductive dysfunction in both wildlife and humans.<sup>[12][13]</sup>

## Types and examples<sup>[[edit](#)]</sup>

- [v](#)
- [t](#)
- [e](#)

Structures of major endogenous estrogens

[Estrone](#) (E1)

[Estradiol](#) (E2)

[Estriol](#) (E3)

[Estetrol](#) (E4)

Note the [hydroxyl](#) (–OH) [groups](#): estrone (E1) has one, estradiol (E2) has two, estriol (E3) has three, and estetrol (E4) has four.

The four major naturally occurring estrogens in women are [estrone](#) (E1), [estradiol](#) (E2), [estriol](#) (E3), and [estetrol](#) (E4). Estradiol (E2) is the predominant estrogen during reproductive years both in terms of absolute serum levels as well as in terms of estrogenic activity. During [menopause](#), estrone is the predominant circulating estrogen and during pregnancy estriol is the predominant circulating estrogen in terms of serum levels. Given by [subcutaneous injection](#) in mice, estradiol is about 10-fold more potent than estrone and about 100-fold more potent than estriol.<sup>[14]</sup> Thus, estradiol is the most important estrogen in non-pregnant females who are between the [menarche](#) and menopause stages of life. However, during [pregnancy](#) this role shifts to estriol, and in postmenopausal women estrone becomes the primary form of estrogen in the body. Another type of estrogen called [estetrol](#) (E4) is produced only during pregnancy. All of the different forms of estrogen are synthesized from [androgens](#), specifically [testosterone](#) and [androstenedione](#), by the [enzyme aromatase](#).

Minor endogenous estrogens, the biosyntheses of which do not involve [aromatase](#), include [27-hydroxycholesterol](#), [dehydroepiandrosterone](#) (DHEA), [7-oxo-DHEA](#), [7 \$\alpha\$ -hydroxy-DHEA](#), [16 \$\alpha\$ -hydroxy-DHEA](#), [7 \$\beta\$ -hydroxyepiandrosterone](#), [androstenedione](#) (A4), [androstenediol](#) (A5), [3 \$\alpha\$ -](#)

[androstenediol](#), and [3 \$\beta\$ -androstenediol](#).<sup>[15][16]</sup> Some estrogen metabolites, such as the [catechol estrogens](#) [2-hydroxyestradiol](#), [2-hydroxyestrone](#), [4-hydroxyestradiol](#), and [4-hydroxyestrone](#), as well as [16 \$\alpha\$ -hydroxyestrone](#), are also estrogens with varying degrees of activity.<sup>[17]</sup> The biological importance of these minor estrogens is not entirely clear.

## Biological function<sup>[edit]</sup>

[Reference ranges for the blood content](#) of estradiol, the primary type of estrogen, during the [menstrual cycle](#).<sup>[18]</sup>

The actions of estrogen are mediated by the [estrogen receptor](#) (ER), a dimeric nuclear protein that binds to DNA and controls [gene expression](#). Like other steroid hormones, estrogen enters passively into the cell where it binds to and activates the estrogen receptor. The estrogen:ER complex binds to specific DNA sequences called a [hormone response element](#) to activate the transcription of target genes (in a study using an estrogen-dependent breast cancer cell line as model, 89 such genes were identified).<sup>[19]</sup> Since estrogen enters all cells, its actions are dependent on the presence of the ER in the cell. The ER is expressed in specific tissues including the ovary, uterus and breast. The metabolic effects of estrogen in postmenopausal women have been linked to the genetic polymorphism of the ER.<sup>[20]</sup>

While estrogens are present in both [men](#) and [women](#), they are usually present at significantly higher levels in women of reproductive age. They promote the development of female [secondary sexual characteristics](#), such as [breasts](#), and are also involved in the thickening of the [endometrium](#) and other aspects of regulating the menstrual cycle. In males, estrogen regulates certain functions of the [reproductive system](#) important to the maturation of [sperm](#)<sup>[21][22][23]</sup> and may be necessary for a healthy [libido](#).<sup>[24]</sup>

## Overview of actions[\[edit\]](#)

This section is in [list](#) format but may read better as [prose](#). You can help by [converting this section](#), if appropriate. [Editing help](#) is available. (October 2019)

- Structural
  - [Anabolic](#): Increases [muscle mass](#) and strength, speed of muscle regeneration, and [bone density](#), increased sensitivity to exercise, protection against muscle damage, stronger [collagen](#) synthesis, increases the collagen content of [connective tissues](#), [tendons](#), and [ligaments](#), but also decreases stiffness of [tendons](#) and [ligaments](#) (especially during [menstruation](#)). Decreased stiffness of tendons gives women much lower predisposition to muscle strains but soft ligaments are much more prone to injuries ([ACL](#) tears are 2-8x more common among women than men). <sup>[25][26][27][28]</sup>
  - Anti-inflammatory properties
  - Mediate formation of female [secondary sex characteristics](#)
  - Accelerate [metabolism](#)
  - Increased [fat storage](#) in some body parts such as breasts, buttocks, and legs but decreased abdominal and [visceral fat](#) (androgenic obesity). <sup>[29][30][31]</sup> [Estradiol](#) also regulates energy expenditure, body weight [homeostasis](#), and seems to have much stronger anti-obesity effects than testosterone in general. <sup>[32]</sup>
- Women tend to have lower base strength but on average have about the same increases of muscle mass in responses to resistance training as men and far faster relative increases in strength. <sup>[33][34]</sup>
  - Stimulate [endometrial](#) growth
  - Increase [uterine](#) growth
  - Increase [vaginal lubrication](#)
  - Thicken the [vaginal](#) wall
  - Maintenance of vessel and skin
  - Reduce [bone resorption](#), increase bone formation
- [Protein](#) synthesis
  - Increase [hepatic production](#) of [binding proteins](#)
- [Coagulation](#)
  - Increase circulating level of [factors 2, 7, 9, 10](#), [plasminogen](#)
  - Decrease [antithrombin III](#)
  - Increase [platelet](#) adhesiveness
  - Increase [vWF](#) (estrogen -> [Angiotensin II](#) -> [Vasopressin](#))

- Increase [PAI-1](#) and [PAI-2](#) also through Angiotensin II
- [Lipid](#)
  - Increase [HDL](#), [triglyceride](#)
  - Decrease [LDL](#), fat deposition
- Fluid balance
  - Salt ([sodium](#)) and water retention
  - Increase [cortisol](#), [SHBG](#)
- [Gastrointestinal tract](#)
  - Reduce bowel motility
  - Increase [cholesterol](#) in [bile](#)
- [Melanin](#)
  - Increase [pheomelanin](#), reduce [eumelanin](#)
- Cancer
  - Support hormone-sensitive breast cancers (see section below)
- [Lung function](#)
  - Promotes lung function by supporting [alveoli](#) (in rodents but probably in humans).<sup>[35]</sup>
- [Uterus](#) lining
  - Estrogen together with [progesterone](#) promotes and maintains the uterus lining in preparation for implantation of fertilized egg and maintenance of uterus function during gestation period, also upregulates [oxytocin](#) receptor in myometrium
- [Ovulation](#)
  - Surge in estrogen level induces the release of [luteinizing hormone](#), which then triggers ovulation by releasing the egg from the [Graafian follicle](#) in the [ovary](#).
- [Sexual behavior](#)
  - Estrogen is required for female mammals to engage in [lordosis behavior](#) during [estrus](#) (when animals are "in heat").<sup>[36][37]</sup> This behavior is required for sexual receptivity in these mammals and is regulated by the [ventromedial nucleus](#) of the [hypothalamus](#).<sup>[38]</sup>
  - [Sex drive](#) is dependent on [androgen](#) levels<sup>[39]</sup> only in the presence of estrogen, but without estrogen, free testosterone level actually decreases sexual desire (instead of increases sex drive), as demonstrated for those women who have [hypoactive sexual desire disorder](#), and the sexual desire in these women can be restored by administration of estrogen (using oral contraceptive).<sup>[40]</sup>

## Female pubertal development<sup>[edit]</sup>

Estrogens are responsible for the development of female [secondary sexual characteristics](#) during [puberty](#), including [breast development](#), widening of the [hips](#), and female [fat distribution](#). Conversely, [androgens](#) are responsible for [pubic](#) and [body hair growth](#), as well as [acne](#) and [axillary odor](#).

### Breast development<sup>[edit]</sup>

See also: [Breast development § Biochemistry](#)

Estrogen, in conjunction with [growth hormone](#) (GH) and its secretory product [insulin-like growth factor 1](#) (IGF-1), is critical in mediating breast development during [puberty](#), as well as breast maturation during [pregnancy](#) in preparation of [lactation](#) and [breastfeeding](#).<sup>[41][42]</sup> Estrogen is primarily and directly responsible for

inducing the ductal component of breast development,<sup>[43][44][45]</sup> as well as for causing [fat deposition](#) and [connective tissue](#) growth.<sup>[43][44]</sup> It is also indirectly involved in the lobuloalveolar component, by increasing [progesterone receptor](#) expression in the breasts<sup>[43][45][46]</sup> and by inducing the secretion of [prolactin](#).<sup>[47][48]</sup> Allowed for by estrogen, [progesterone](#) and prolactin work together to complete lobuloalveolar development during pregnancy.<sup>[44][49]</sup>

[Androgens](#) such as testosterone powerfully oppose estrogen action in the breasts, such as by reducing [estrogen receptor](#) expression in them.<sup>[50][51]</sup>

## Female reproductive system<sup>[edit]</sup>

Estrogens are responsible for maturation and maintenance of the [vagina](#) and [uterus](#), and are also involved in [ovarian](#) function, such as maturation of [ovarian follicles](#). In addition, estrogens play an important role in regulation of [gonadotropin secretion](#). For these reasons, estrogens are required for female [fertility](#).

## Neuroprotection and DNA repair<sup>[edit]</sup>

Estrogen regulated [DNA repair](#) mechanisms in the [brain](#) have neuroprotective effects.<sup>[52]</sup> Estrogen regulates the [transcription](#) of DNA [base excision repair](#) genes as well as the translocation of the base excision repair enzymes between different subcellular compartments.

## Brain and behavior<sup>[edit]</sup>

### Sex drive<sup>[edit]</sup>

See also: [Sexual motivation and hormones](#)

Estrogens are involved in [libido](#) (sex drive) in both women and men.

### Cognition<sup>[edit]</sup>

[Verbal memory](#) scores are frequently used as one measure of higher level [cognition](#). These scores vary in direct proportion to estrogen levels throughout the menstrual cycle, pregnancy, and menopause. Furthermore, estrogens when administered shortly after natural or surgical menopause prevents decreases in verbal memory. In contrast, estrogens have little effect on verbal memory if first administered years after menopause.<sup>[53]</sup> Estrogens also have positive influences on other measures of cognitive function.<sup>[54]</sup> However the effect of estrogens on cognition is not uniformly favorable and is dependent on the timing of the dose and the type of cognitive skill being measured.<sup>[55]</sup>

The protective effects of estrogens on cognition may be mediated by estrogen's anti-inflammatory effects in the brain.<sup>[56]</sup> Studies have also shown that the Met allele gene and level of estrogen mediates the efficiency of [prefrontal cortex](#) dependent working memory tasks.<sup>[57][58]</sup> Researchers have urged for further research to illuminate the role of estrogen and its potential for improvement on cognitive function.<sup>[59]</sup>

### Mental health<sup>[edit]</sup>

Estrogen is considered to play a significant role in women's [mental health](#). Sudden estrogen withdrawal, fluctuating estrogen, and [periods](#) of sustained low estrogen levels

correlate with a significant lowering of mood. Clinical recovery from [postpartum](#), [perimenopause](#), and [postmenopause](#) depression has been shown to be effective after levels of estrogen were stabilized and/or restored.<sup>[60][61][62]</sup> [Menstrual exacerbation \(including menstrual psychosis\)](#) is typically triggered by low estrogen levels,<sup>[63]</sup> and is often mistaken for [premenstrual dysphoric disorder](#).<sup>[64]</sup>

Compulsions in male lab mice, such as those in obsessive-compulsive disorder (OCD), may be caused by low estrogen levels. When estrogen levels were raised through the increased activity of the enzyme [aromatase](#) in male lab mice, OCD rituals were dramatically decreased. [Hypothalamic](#) protein levels in the gene [COMT](#) are enhanced by increasing estrogen levels which are believed to return mice that displayed OCD rituals to normal activity. Aromatase deficiency is ultimately suspected which is involved in the synthesis of estrogen in humans and has therapeutic implications in humans having obsessive-compulsive disorder.<sup>[65]</sup>

Local application of estrogen in the rat hippocampus has been shown to inhibit the re-uptake of [serotonin](#). Contrarily, local application of estrogen has been shown to block the ability of [fluvoxamine](#) to slow serotonin clearance, suggesting that the same pathways which are involved in SSRI efficacy may also be affected by components of local estrogen signaling pathways.<sup>[66]</sup>

### **Parenthood**[\[edit\]](#)

Studies have also found that fathers had lower levels of cortisol and testosterone but higher levels of estrogen (estradiol) than did non-fathers.<sup>[67]</sup>

### **Binge eating**[\[edit\]](#)

Estrogen may play a role in suppressing [binge eating](#). Hormone replacement therapy using estrogen may be a possible treatment for binge eating behaviors in females. Estrogen replacement has been shown to suppress binge eating behaviors in female mice.<sup>[68]</sup> The mechanism by which estrogen replacement inhibits binge-like eating involves the replacement of [serotonin](#) (5-HT) neurons. Women exhibiting binge eating behaviors are found to have increased brain uptake of neuron 5-HT, and therefore less of the neurotransmitter serotonin in the cerebrospinal fluid.<sup>[69]</sup> Estrogen works to activate 5-HT neurons, leading to suppression of binge like eating behaviors.<sup>[68]</sup>

It is also suggested that there is an interaction between hormone levels and eating at different points in the female [menstrual cycle](#). Research has predicted increased emotional eating during hormonal flux, which is characterized by high [progesterone](#) and [estradiol](#) levels that occur during the mid-[luteal phase](#). It is hypothesized that these changes occur due to brain changes across the menstrual cycle that are likely a genomic effect of hormones. These effects produce menstrual cycle changes, which result in hormone release leading to behavioral changes, notably binge and emotional eating. These occur especially prominently among women who are genetically vulnerable to binge eating phenotypes.<sup>[70]</sup>

Binge eating is associated with decreased estradiol and increased progesterone.<sup>[71]</sup> Klump et al.<sup>[72]</sup> Progesterone may moderate the effects of low estradiol (such as during dysregulated eating behavior), but that this may only be true in women

who have had clinically diagnosed binge episodes (BEs). Dysregulated eating is more strongly associated with such ovarian hormones in women with BEs than in women without BEs.<sup>[72]</sup>

The implantation of 17 $\beta$ -estradiol pellets in ovariectomized mice significantly reduced binge eating behaviors and injections of GLP-1 in ovariectomized mice decreased binge-eating behaviors.<sup>[68]</sup>

The associations between binge eating, menstrual-cycle phase and ovarian hormones correlated.<sup>[71][73][74]</sup>

### **Masculinization in rodents**[\[edit\]](#)

In rodents, estrogens (which are locally aromatized from androgens in the brain) play an important role in psychosexual differentiation, for example, by masculinizing territorial behavior;<sup>[75]</sup> the same is not true in humans.<sup>[76]</sup> In humans, the masculinizing effects of prenatal androgens on behavior (and other tissues, with the possible exception of effects on bone) appear to act exclusively through the androgen receptor.<sup>[77]</sup> Consequently, the utility of rodent models for studying human psychosexual differentiation has been questioned.<sup>[78]</sup>

### **Skeletal system**[\[edit\]](#)

Estrogens are responsible for both the pubertal growth spurt, which causes an acceleration in linear growth, and [epiphyseal closure](#), which limits [height](#) and [limb](#) length, in both females and males. In addition, estrogens are responsible for bone maturation and maintenance of [bone mineral density](#) throughout life. Due to hypoestrogenism, the risk of [osteoporosis](#) increases during [menopause](#).

### **Cardiovascular system**[\[edit\]](#)

Women are less impacted by heart disease due to vasculo-protective action of estrogen which helps in preventing atherosclerosis.<sup>[79]</sup> It also helps in maintaining the delicate balance between fighting infections and protecting arteries from damage thus lowering the risk of cardiovascular disease.<sup>[80]</sup> During [pregnancy](#), high levels of estrogens increase [coagulation](#) and the risk of [venous thromboembolism](#). Estrogen has been shown to upregulate the [peptide hormone adropin](#).<sup>[81]</sup>

- [v](#)
- [t](#)
- [e](#)

**Absolute and relative incidence of venous thromboembolism (VTE) during pregnancy and the postpartum period show**

### **Immune system**[\[edit\]](#)

The effect of estrogen on the [immune system](#) is in general described as [Th2](#) favoring, rather than suppressive, as is the case of the effect of male sex hormone - testosterone.<sup>[83]</sup> Indeed women respond better to [vaccines](#), [infections](#) and are generally less likely to develop [cancer](#), the tradeoff of this is that they are more likely to develop an [autoimmune disease](#).<sup>[84]</sup> The [Th2](#) shift manifests itself in a decrease of cellular

immunity and increase in humoral immunity ([antibody](#) production) shifts it from cellular to humoral by downregulating cell-mediated immunity and enhancing Th2 immune response by stimulating IL-4 production and Th2 differentiation.<sup>[83][85]</sup> [Type 1](#) and [type 17](#) immune responses are downregulated, likely to be at least partially due to [IL-4](#), which inhibits Th1. Effect of estrogen on different immune cells' cell types is in line with its Th2 bias. Activity of [basophils](#), [eosinophils](#), M2 [macrophages](#) and is enhanced, whereas activity of [NK cells](#) is downregulated. Conventional [dendritic cells](#) are biased towards Th2 under the influence of estrogen, whereas plasmacytoid dendritic cells, key players in antiviral defence, have increased [IFN-γ](#) secretion.<sup>[85]</sup> Estrogen also influences [B cells](#) by increasing their survival, proliferation, differentiation and function, which corresponds with higher antibody and B cell count generally detected in women.<sup>[86]</sup>

On a molecular level estrogen induces the above mentioned effects on cell via acting on intracellular [receptors](#) termed ER α and ER β, which upon ligation form either homo or heterodimers. The genetic and nongenetic targets of the receptors differ between homo and heterodimers.<sup>[87]</sup> Ligation of these receptors allows them to translocate to the [nucleus](#) and act as [transcription factors](#) either by binding estrogen response elements (ERE) on [DNA](#) or binding DNA together with other transcriptional factors e.g. [Nf-kB](#) or [AP-1](#), both of which result in [RNA polymerase](#) recruitment and further [chromatin remodeling](#).<sup>[87]</sup> A non-transcriptional response to oestrogen stimulation was also documented (termed membrane-initiated steroid signalling, MISS). This pathway stimulates the ERK and PI3K/AKT pathways, which are known to increase cellular proliferation and affect chromatin remodeling.<sup>[87]</sup>

## Associated conditions<sup>[edit]</sup>

Researchers have implicated estrogens in various [estrogen-dependent conditions](#), such as ER-positive [breast cancer](#), as well as a number of [genetic conditions](#) involving estrogen signaling or metabolism, such as [estrogen insensitivity syndrome](#), [aromatase deficiency](#), and [aromatase excess syndrome](#).

High estrogen can amplify [stress-hormone](#) responses in stressful situations.<sup>[88]</sup>

## Biochemistry<sup>[edit]</sup>

---

See also: [Estradiol § Biochemistry](#)

## Biosynthesis<sup>[edit]</sup>

[Steroidogenesis](#), showing estrogens at bottom right as in pink triangle.<sup>[89]</sup>

Estrogens, in females, are produced primarily by the [ovaries](#), and during pregnancy, the [placenta](#).<sup>[90]</sup> [Follicle-stimulating hormone](#) (FSH) stimulates the ovarian production of estrogens by the [granulosa cells](#) of the [ovarian follicles](#) and [corpora lutea](#). Some estrogens are also produced in smaller amounts by other tissues such as the [liver](#), [pancreas](#), [bone](#), [adrenal glands](#), [skin](#), [brain](#), [adipose tissue](#),<sup>[91]</sup> and the [breasts](#).<sup>[92]</sup> These secondary sources of estrogens are especially important in postmenopausal women.<sup>[93]</sup> The pathway of estrogen biosynthesis in extragonadal tissues is different. These tissues are not able to synthesize C19 steroids, and therefore depend on C19 supplies from other tissues<sup>[93]</sup> and the level of aromatase.<sup>[94]</sup>

In females, synthesis of estrogens starts in [theca interna](#) cells in the ovary, by the synthesis of [androstenedione](#) from [cholesterol](#). Androstenedione is a substance of weak androgenic activity which serves predominantly as a [precursor](#) for more potent androgens such as testosterone as well as estrogen. This compound crosses the [basal membrane](#) into the surrounding granulosa cells, where it is converted either immediately into estrone, or into testosterone and then estradiol in an additional step. The conversion of androstenedione to testosterone is catalyzed by [17 \$\beta\$ -hydroxysteroid dehydrogenase](#) (17 $\beta$ -HSD), whereas the conversion of androstenedione and testosterone into estrone and estradiol, respectively is catalyzed by aromatase, enzymes which are both expressed in granulosa cells. In contrast, granulosa cells lack [17 \$\alpha\$ -hydroxylase](#) and [17,20-lyase](#), whereas theca cells express these enzymes and 17 $\beta$ -HSD but lack aromatase. Hence, both granulosa and theca cells are essential for the production of estrogen in the ovaries.

Estrogen levels vary through the [menstrual cycle](#), with levels highest near the end of the [follicular phase](#) just before [ovulation](#).

Note that in males, estrogen is also produced by the [Sertoli cells](#) when FSH binds to their FSH receptors.

• [v](#)

## Distribution[\[edit\]](#)

Estrogens are [plasma protein bound](#) to [albumin](#) and/or [sex hormone-binding globulin](#) in the circulation.

## Metabolism[\[edit\]](#)

See also: [Estradiol § Metabolism](#), and [Estradiol \(medication\) § Metabolism](#)

Estrogens are [metabolized](#) via [hydroxylation](#) by [cytochrome P450 enzymes](#) such as [CYP1A1](#) and [CYP3A4](#) and via [conjugation](#) by [estrogen sulfotransferases](#) ([sulfation](#)) and [UDP-glucuronyltransferases](#) ([glucuronidation](#)). In addition, estradiol is [dehydrogenated](#) by [17β-hydroxysteroid dehydrogenase](#) into the much less potent estrogen estrone. These reactions occur primarily in the [liver](#), but also in other [tissues](#).

**Description:** The [metabolic pathways](#) involved in the [metabolism](#) of [estradiol](#) and other [natural](#) estrogens (e.g., [estrone](#), [estriol](#)) in humans. In addition to the [metabolic transformations](#) shown in the diagram, [conjugation](#) (e.g., [sulfation](#) and [glucuronidation](#)) occurs in the case of estradiol and [metabolites](#) of estradiol that have one or more available [hydroxyl](#) (–OH) [groups](#). **Sources:** See template page.

## Excretion<sup>[\[edit\]](#)</sup>

Estrogens are [excreted](#) primarily by the [kidneys](#) as [conjugates](#) via the [urine](#).

## Medical use<sup>[\[edit\]](#)</sup>

*Main article:* [Estrogen \(medication\)](#)

Estrogens are used as [medications](#), mainly in [hormonal contraception](#), [hormone replacement therapy](#),<sup>[\[95\]](#)</sup> and to treat gender dysphoria in [transgender women](#) and other [transfeminine individuals](#) as part of feminizing hormone therapy.<sup>[\[96\]](#)</sup>

## Chemistry<sup>[edit]</sup>

---

See also: [List of estrogens](#)

The estrogen steroid hormones are [estrane steroids](#).

## History<sup>[edit]</sup>

---

See also: [Estradiol § History](#), [Estrone § History](#), and [Estrogen \(medication\) § History](#)

In 1929, [Adolf Butenandt](#) and [Edward Adelbert Doisy](#) independently isolated and purified estrone, the first estrogen to be discovered.<sup>[97]</sup> Then, estriol and estradiol were discovered in 1930 and 1933, respectively. Shortly following their discovery, estrogens, both natural and synthetic, were introduced for medical use. Examples include [estriol glucuronide](#) ([Emmenin](#), [Progyonon](#)), [estradiol benzoate](#), [conjugated estrogens](#) ([Premarin](#)), [diethylstilbestrol](#), and [ethinylestradiol](#).

The word estrogen derives from [Ancient Greek](#). It is derived from "oestros"<sup>[98]</sup> (a periodic state of sexual activity in female mammals), and genos (generating).<sup>[98]</sup> It was first published in the early 1920s and referenced as "oestrin".<sup>[99]</sup> With the years, American English adapted the spelling of estrogen to fit with its phonetic pronunciation. Nevertheless, both estrogen and oestrogen are used nowadays, yet some still wish to maintain its original spelling as it reflects the origin of the word.

## Society and culture<sup>[edit]</sup>

---

### Etymology<sup>[edit]</sup>

The name *estrogen* is derived from the [Greek](#) οἶστρος (*oîstros*), literally meaning "verve" or "inspiration" but figuratively sexual passion or desire,<sup>[100]</sup> and the suffix *-gen*, meaning "producer of".

### Environment<sup>[edit]</sup>

A range of synthetic and natural substances that possess estrogenic activity have been identified in the [environment](#) and are referred to [xenoestrogens](#).<sup>[101]</sup>

- Synthetic substances such as [bisphenol A](#) as well as [metalloestrogens](#) (e.g., [cadmium](#)).
- Plant products with estrogenic activity are called [phytoestrogens](#) (e.g., [coumestrol](#), [daidzein](#), [genistein](#), [miroestrol](#)).
- Those produced by fungi are known as [mycoestrogens](#) (e.g., [zearalenone](#)).

Estrogens are among the wide range of [endocrine-disrupting compounds](#) (EDCs) because they have high estrogenic potency. When an EDC makes its way into the environment, it may cause male reproductive dysfunction to wildlife and humans.<sup>[12][13]</sup> The estrogen excreted from farm animals makes its way into fresh water systems.<sup>[102]</sup> During the germination period of reproduction the fish are exposed to low levels of estrogen which may cause reproductive dysfunction to male fish.<sup>[103][104]</sup>

### Cosmetics<sup>[edit]</sup>

Some hair [shampoos](#) on the market include estrogens and placental extracts; others contain [phytoestrogens](#). In 1998, there were case reports of four prepubescent African-American girls developing breasts after exposure to these shampoos.<sup>[105]</sup> In 1993, the FDA determined that not all [over-the-counter](#) topically applied hormone-containing drug products for human use are [generally recognized as safe and effective](#) and are misbranded. An accompanying proposed rule deals with cosmetics, concluding that any use of natural estrogens in a cosmetic product makes the product an unapproved new drug and that any cosmetic using the term "hormone" in the text of its labeling or in its ingredient statement makes an implied drug claim, subjecting such a product to regulatory action.<sup>[106]</sup>

In addition to being considered misbranded drugs, products claiming to contain placental extract may also be deemed to be misbranded cosmetics if the extract has been prepared from placentas from which the hormones and other biologically active substances have been removed and the extracted substance consists principally of protein. The FDA recommends that this substance be identified by a name other than "placental extract" and describing its composition more accurately because consumers associate the name "placental extract" with a therapeutic use of some biological activity.<sup>[106]</sup>

Estrogen is a generic term for any of three similar hormones derived from cholesterol: estradiol, estrone, and estriol.
2. <sup>^</sup> Satoskar RS, Rege N, Bhandarkar SD (2017). *Pharmacology and Pharmacotherapeutics*. Elsevier Health Sciences. p. 943. [ISBN 978-8-13-124941-3](#). The natural estrogens are steroids. However, typical estrogenic activity is also shown by chemicals which are not steroids. Hence, the term 'estrogen' is used as a generic term to describe all the compounds having estrogenic activity.
3. <sup>^</sup> Delgado BJ, Lopez-Ojeda W (20 December 2021). *"Estrogen"*. StatPearls [Internet]. StatPearls Publishing. [PMID 30855848](#). Estrogen is a steroid hormone associated with the female reproductive organs and is responsible for the development of female sexual characteristics. Estrogen is often referred to as estrone, estradiol, and estriol. ... Synthetic estrogen is also available for clinical use, designed to increase absorption and effectiveness by altering the estrogen chemical structure for topical or oral administration. Synthetic steroid estrogens include ethinyl estradiol, estradiol valerate, estropipate, conjugate esterified estrogen, and quinestrol.
